#### 1. Introduction

The technical result [2, Lemma 3.2] of Gabriel, called often Gabriel's Lemma (for the precise formulation see Section 2), played a crucial role in proofs of two famous theorems in representation theory of algebras: the theorem of Gabriel on openness of the set of finite representation type algebras in a variety of all algebras with a fixed dimension (see [2]) and the Geiss Theorem saying that degeneration of a wild algebra is also wild (see [3]). The original proof of Gabriel's Lemma is rather involved and uses geometry of schemes. An alternative proof, proposed by H. Kraft for the case of characteristic 0, applies essentially invariant theory and geometric quotients (see [5]). We present here a new, quite simple proof, which uses only basic projective geometry and adapts some arguments presented in [1].

For basic information concerning algebraic geometry and algebraic groups we refer to [4, 6].

We fix now some notations. Let K be an algebraically closed field,  $d, z \in \mathbb{N}$  natural numbers, Gl(z) a connected affine algebraic group of K-linear automorphisms of the vector space  $K^z$ . We consider the set

$$alg(d) = \{c = (c_{ij}^k) \in K^{d^3} \mid c \text{ satisfies (i) and (ii) below } \}$$

192 A. HAJDUK

where

(i) 
$$\sum_{s=1}^{d} c_{ij}^{s} c_{sk}^{l} = \sum_{s=1}^{d} c_{is}^{k} c_{jl}^{s}$$

(ii) 
$$\exists \alpha_1, \dots, \alpha_d \in K \quad \sum_{i=1}^d \alpha_i c_{ij}^k = \delta_{jk} = \begin{cases} 0 & \text{if } i = j \\ 1 & \text{if } i \neq j \end{cases}$$

for  $1 \le i, j, k, l \le d$ . It is known that alg(d) is an affine variety called a variety of algebras. For any element  $c \in alg(d)$  corresponds a unique associative algebra structure A(c) on  $K^d$  admitting a unit element, where multiplication on basic elements  $e_1, \ldots, e_d \in K^d$  is determined by the equations  $e_i \cdot_{A(c)} e_j =$  $\sum_{k=1}^{d} c_{ij}^{k} \cdot e_{k} \text{ for } 1 \leq i, j \leq d.$  For any  $c \in \text{alg}(d)$  we set

$$\operatorname{mod}_{c}(z) = \{ M = (M_{i}) \in \operatorname{End}_{K}(K^{z})^{d} \mid M \text{ satisfies (a) and (b) below} \}$$

(a) 
$$\forall i, j \ M_i \cdot M_j = \sum_{l=1}^d c_{ij}^l M_l$$

(b) 
$$\alpha_1 M_1 + \alpha_2 M_2 + \ldots + \alpha_d M_d = I_d$$

where  $\alpha_1, \ldots, \alpha_d \in K$  are obtained from condition (ii) in definition of the variety alg(d). It is clear that any sequence  $(M_i)$  defines an A(c)-module structure on  $K^z$ , where the matrix  $M_i$  corresponds to the action of the base element  $e_i$  of algebra A(c) on vector space  $K^z$ . This mapping yields a bijection between mod c(z) and all A(c)-module structures on  $K^z$ . The set mod c(z) is an affine variety. The algebraic group Gl(z) acts regularly on the variety  $\operatorname{mod}_{c}(z)$  by simultaneous conjugation of all matrices defining a given A(c)module structure, two elements in  $\text{mod}_{c}(z)$  belong to the same orbit if and only if the respective A(c)-modules are isomorphic.

Suppose that we have an A(c)-module W of dimension z with K-linear ordered base  $\underline{w} = (w_1, \dots, w_z) \in W^z$ . By  $M(W, \underline{w})$  we mean the element of mod c(z) corresponding to A(c)-module  $K^z$  with the structure transferred by the isomorphism of vector spaces W and  $K^z$ , which maps the consecutive elements of base  $\underline{w}$  to adequate elements of standard base of  $K^z$ .

We define also a variety

$$\operatorname{algmod}(d, z) = \{(c, M) \mid c \in \operatorname{alg}(d) \ M \in \operatorname{mod}_{c}(z)\}.$$

On algmod (d, z) we have the induced Gl(z)-action.

### 2. The Proof of Gabriel's Lemma

Before we present the announced proof we recall the precise formulation of Gabriel result.

THEOREM. (GABRIEL'S LEMMA) Projection

$$\pi: \operatorname{algmod}(d, z) \to \operatorname{alg}(d), \ (c, M) \mapsto c$$

maps closed and Gl(z)-invariant subsets into closed subsets.

*Proof.* We set

$$Sur(dz, z) = \{ S \in Hom_k((K^d)^z, K^z) \mid Im S = K^z \}$$

Clearly, Sur(dz, z) is a quasi-affine variety which is equipped with the regular action of Gl(z) induced by the canonical action of Gl(z) on  $K^z$ .

Let Z be the subset of  $alg(d) \times Sur(dz, z)$  consisting of all pairs (c, S) such that Ker S is an A(c)-submodule of a free module  $A(c)^z$ , where  $A(c)^z = (K^d)^z$  as a vector space. In the space  $(K^d)^z$  we have a canonical linear base which consists of vectors  $\{e_i^j\}$  (i = 1, ..., d; j = 1, ..., z), where the sequence  $\{e_i^j\}$  (i = 1, ..., d) forms a standard base of j-th coordinate of a product

$$(K^d)^z = \underbrace{K^d \times \cdots \times K^d}_{\text{z times}}$$

for every  $j = 1, \ldots, z$ .

Any sequence  $u = (u_t) \in \{e_i^j\}^z$  consisting of z pairwise different elements, defines an open subset  $V_u \subset \operatorname{Sur}(dz,z)$  formed by all elements  $S \in \operatorname{Sur}(dz,z)$  for which determinant of the matrix

$$g(u)(S) = [S(u_1), \dots, S(u_z)] \in M_z(K)$$

is nonzero. In this way we get open coverings

$$\operatorname{Sur}(dz,z) = \bigcup_{u} V_u$$

and

$$alg(d) \times Sur(dz, z) = \bigcup_{u} alg(d) \times V_{u}$$

194 A. HAJDUK

of the varieties alg(d) and  $alg(d) \times Sur(dz, z)$ , respectively. Moreover, we have an action of Gl(z) on the variety  $alg(d) \times Sur(dz, z)$  induced by the action of Gl(z) on Sur(dz, z). Note that the set Z is Gl(z)-invariant, since for any  $S \in Sur(dz, z)$  the kernel ker S is a Gl(z)-invariant element of Gr(dz - z, dz) under the induced action on Gr(dz - z, dz) which maps the pair  $(g, \ker S)$  to element ker gS for any  $g \in Gl(z)$  (in the other words this map is a trivial action on Gr(dz-z,dz)). We show now that the set Z is closed in  $alg(d) \times Sur(dz,z)$ . It is sufficient to show, that Z is locally closed with respect to above open covering of the set  $alg(d) \times Sur(dz,z)$ .

For any  $S \in \text{Sur}(dz, z)$ , S belongs to  $V_u$  exactly when  $S_u = S_{|\text{span}(u)|}$  is an isomorphism. Therefore we have  $(c, S) \in Z \cap (\text{alg}(d) \times V_u)$  if and only if  $(c, S) \in \psi_{(u, i, v)}^{-1}((0, \dots, 0))$  for all  $1 \leq i \leq d, v \in \{e_i^j\}$ , where

$$\psi_{(u,i,v)}: alg(d) \times V_u \to K^z$$

is given by  $\psi_{(u,i,v)}(c,S) = S(e_i \cdot_c (v - S_u^{-1}(S(v))))$  ( $\cdot_c$  denotes here an A(c)-module multiplication in a free A(c)-module  $(K^d)^z$ ). Consequently  $Z \cap (\operatorname{alg}(d) \times V_u)$  is closed and Z is locally closed.

We define now a partial function  $\varphi_u: Z \dashrightarrow \operatorname{algmod}(d, z)$ , which is given by the formula

$$\varphi_u(c,S) = (c, M(W_{(c,S)}, \underline{w}_{(c,S)}))$$

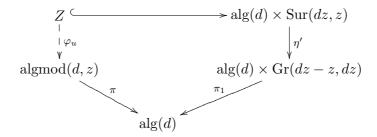

for  $(c,S) \in Z \cap (\operatorname{alg}(d) \times V_u)$ , where  $W_{(c,S)} = (K^d)^z/\operatorname{Ker} S$  and  $\underline{w}_{(c,S)} = (u_1 + \operatorname{Ker} S, \dots, u_z + \operatorname{Ker} S)$ . We show now that  $\varphi_u$  is regular on its domain  $\mathcal{D}_u$ . Clearly,  $\mathcal{D}_u = Z \cap (\operatorname{alg}(d) \times V_u)$  forms an open set in Z. Notice also that  $\operatorname{Ker} S = \operatorname{span}(\{e_i^j - S_u^{-1}(S(e_i^j))\}_{e_i^j \notin \{u_1, \dots, u_z\}})$  and that

$$\underline{M_i}(u_j + \operatorname{Ker} S) = e_i \cdot_c u_j - \sum_{k,l;e_k^l \in u'} \left[ (e_i \cdot_c u_j)_k^l \cdot (e_k^l - S_u^{-1}(S(e_k^l))) \right] + \operatorname{Ker} S$$

where  $(\underline{M_i})_{i=1,\dots,d} = M(W_{(c,S)},\underline{w}_{(c,S)}), \ u' = \{e_i^j\} \setminus \{u_1,\dots,u_z\}$  and elements  $v_k^l \in K$  satisfy the equation  $v = \sum_{i,j} v_i^j \cdot e_i^j$  for  $v \in (K^d)^z$ . Consequently,  $\underline{M_i}(u_j + \operatorname{Ker} S)$  depends regularly on  $(c,S) \in Z \cap (\operatorname{alg}(d) \times V_u)$  and  $\varphi_{u|\mathcal{D}_u} : \overline{\mathcal{D}_u} \to \operatorname{algmod}(d,z)$  is regular.

Now we can complete our proof. We carry out our reasoning in similarly way as in [1]. Let  $\eta: \operatorname{Sur}(dz, z) \to \operatorname{Gr}(dz - z, dz)$  be a map given by  $\eta(S) = \operatorname{Ker} S$  for  $S \in \operatorname{Sur}(dz, z)$ , where  $\operatorname{Gr}(dz - z, dz)$  is a Grassmann variety (see [4, 6]). The map  $\eta$  is locally a projection (Z is covered by the sets of the

form  $\mathcal{D}_u$ , see also [1, Lemma 2]) and therefore so is the induced product  $\eta' = \mathrm{id} \times \eta : \mathrm{alg}(d) \times \mathrm{Sur}(dz, z) \to \mathrm{alg}(d) \times \mathrm{Gr}(dz - z, dz)$ . Consequently,  $\eta'$  is an open map. Consider the following family of diagrams

where the horizontal map is a canonical embedding. The map  $\eta'$  is an open surjection with fibres equal to  $\mathrm{Gl}(z)$ -orbit. Fix a closed,  $\mathrm{Gl}(z)$ -invariant subset  $X\subseteq \mathrm{algmod}(d,z)$ . Then the set  $X'=\bigcup_u \varphi_u^{-1}(X)$  is  $\mathrm{Gl}(z)$ -invariant and closed in Z since X' is locally closed with respect to the open covering  $Z=\bigcup_u \mathcal{D}_u$  (for any  $(c,S)\in\mathcal{D}_{u_1}\cap\mathcal{D}_{u_2}$  we have an equality  $\mathrm{Gl}(z)\cdot\varphi_{u_1}(c,S)=\mathrm{Gl}(z)\cdot\varphi_{u_2}(c,S)$  and therefore  $\varphi_{u_2}^{-1}(X)\cap\mathcal{D}_{u_1}\subseteq\varphi_{u_1}^{-1}(X)$ ). Consequently, X' is closed and  $\mathrm{Gl}(z)$ -invariant in  $P=\mathrm{alg}(d)\times\mathrm{Sur}(dz,z)$ , since Z is closed. Hence  $\eta'(X')$  is a closed set as complement of the image  $\eta'(P\setminus X')$ . Finally, by completeness of the variety  $\mathrm{Gr}(dz-z,dz)$ , we infer that  $\pi_1(\eta'(X'))=\pi(X)$  is a closed set.
